Application No. 10/023,992 Amendment dated June 14, 2005 Reply to Office Action dated March 14, 2005

AMENDMENTS TO THE CLAIMS:

This listing of the claims will replace all prior versions, and listings, of claims in the application.

- (Original) A system for enabling a node, adapted for use in a wireless 1. communications network, to detect a data signal in a received signal containing noise, said system comprising:
- a first correlation circuit, adapted to correlate said received signal with a first reference sequence, and output an intermediate correlated signal;
- a second correlation circuit, adapted to correlate said intermediate correlated signal with a second reference sequence, and output a correlated signal;
- a threshold generating circuit, adapted to generate a threshold value based on an estimation of the variance of said intermediate correlated signal over time; and
- a comparison circuit, adapted to compare said correlated signal to said threshold value to determine whether said received signal includes said data signal.
 - (Original) A system as claimed in claim 1, wherein:

said threshold generating circuit includes a variance estimation circuit, adapted to average said intermediate correlated signal over a period of time and output an estimate of the variance signal; and

a scaling circuit, adapted to mathematically combine said estimate of the variance signal with a constant to output said threshold value.

3. (Original) A system as claimed in claim 2, wherein:

said scaling circuit multiplies said estimate of the variance signal with said constant to output said threshold value.

Application No. 10/023,992 Amendment dated June 14, 2005 Reply to Office Action dated March 14, 2005

4. (Original) A system as claimed in claim 1, wherein:

said comparison circuit outputs a detection signal indicating detection of said data signal in said received signal when a level of said correlated signal is at least equal to said threshold value; and

said comparison circuit outputs a non-detection signal indicating non-detection of said data signal in said received signal when a level of said correlated signal is less than said threshold value.

5. (Currently Amended) A method for enabling a node, adapted for use in a wireless communications network, to detect a data signal in a received signal containing noise, said method comprising:

<u>performing</u> a first correlation <u>eireuit</u> <u>operation</u> to correlate said received signal with a first reference sequence, and output an intermediate correlated signal;

<u>performing</u> a second correlation <u>eireuit</u> <u>operation</u> to correlate said intermediate correlated signal with a second reference sequence, and output a correlated signal;

a threshold generating circuit, adapted to generate a threshold value based on an estimate of the variance of said intermediate correlated signal over time; and

comparing said correlated signal to said threshold value to determine whether said received signal includes said data signal.

6. (Currently Amended) A method as claimed in claim 6 5, wherein said threshold generating includes:

estimating the variance of said intermediate correlated signal over a period of time and output an estimate of the variance signal; and

mathematically combining said estimate of the variance signal with a constant to output said threshold value.

7. (Currently Amended) A method as claimed in claim 7 6, wherein: said mathematically combining multiples said estimate of the variance signal with said

constant to output said threshold value.

- 8. (Currently Amended) A method as claimed in claim 6 5, wherein:
 said comparing outputs a detection signal indicating detection of said data signal in said
 received signal when a level of said correlated signal is at least equal to said threshold value; and
 said comparing outputs a non-detection signal indicating non-detection of said data signal
 in said received signal when a level of said correlated signal is less than said threshold value.
- 9. (New) The system as claimed in claim 1, wherein the wireless communication network includes an ad-hoc wireless communication network in which the node is operating, and the first correlation circuit, second correlation circuit, threshold generating circuit and comparison circuit are present at the node.
- 10. (New) A method as claimed in claim 5, wherein the wireless communications network includes an ad-hoc communication network in which the node is operating, and the first correlation operation, second correlation operation, generating and comparing are performed by the node.
